Army Research Office Programs In Beam Technology and Surface Engineering

Robert R. Reeber
Materials Engineer
Army Research Office
Research Triangle Park, NC 27709

The objective here is to provide some idea of needs and opportunities for future research with potential for providing new capabilities for Army systems. The technical objectives of the program are 1. to discover the atomic, molecular and macroscopic processes governing deterioration and adhesion of materials, 2. to provide improved materials stability and longer term performance capability for Army systems, and 3. to educate the next generation of skilled scientists in areas of Army research opportunities and needs.

Two principal thrust areas, (1) Beam Technology and Surface Modification and (2) Non-Destructive Characterization of Materials and Processes, are the templates for fulfilling the technical objectives of the program. New directions in nondestructive characterization, adhesion, non-equilibrium processing of refractory materials, ultrastrong laminates, green processing of corrosion resistant coatings and superhard coatings will be reviewed.

Research at the University of Wisconsin, Milwaukee (Carolyn Aita); has provided a characterization scheme (metastable phase maps) for refractory metal oxide sputter depositions. These results have depended on careful spectroscopic plasma characterization and determination of the crystallinity of films with x-ray, XPS and other methods. The University of Michigan (Bilello, Yalisove and Srolovitz) refractory metals laminates project where synchrotron topography and double crystal diffractometry techniques and theory are being applied to monitor and predict residual stresses and properties of nanolaminate materials.

A current program in chemical analysis with low and medium energy ion beams is underway at Vanderbilt University (Robert Weller). A new form of backscattering spectrometry using medium energy ions and time-of-flight detection has been developed that is particularly useful for characterizing surfaces and thin films. Currently some scaleup of the results is being accomplished with the cooperation of Semitech and Sandia National Laboratory.

A. Chemical/Biological Defense:

Previous work at the University of Connecticut, Koberstein, in the mid to late 1980's was cofunded by the National Science Foundation and related to surface tension measurements of polymer blends. At the same time at Cornell Kramer began seminal work to measure true diffusion coefficients of organics in polymer glasses with Rutherford Back-Scattering Spectrometry. After this work completed new efforts applying positron annihilation methods to polymers were started and are continuing. Their aim is to determine polymer free volume and its relationship to aging and transport in polymers (Case Western Reserve, McGervey, Simha and Jamieson).

B. Surface Modification/Beam Technology:

Although initially work was aimed at identifying unique properties of beam-treated materials, a growing awareness arose concerning environmental problems with plating wastes and the chemical solutions required for routine coating. This caused a

second look at what alternates were available. Some directions were identified that potentially could reduce the costs of the new technology. Lawrence Berkeley Laboratory's Ian Brown, an innovator in high current sources for implantation, was cofunded with the Office of Naval Research to further develop his technology. University of Wisconsin-Madison (John Conrad), has been evaluating the potential of Plasma Ion Implantation (PSII). The Madison group has had continuing transfers of technology to industry (Kearfoot-Singer) for space bearings, the auto industry and direct interactions with Army organizations ie. Corpus Christi Army Depot, Army Materials Technology Laboratory and Rock Island Arsenal. Their method permits non-line-of-sight implantation with relatively uniform doses.

C. Adhesion and Adhesives:

The previous sections as they relate to bonding and coating technology have already touched on some of the approaches to improved adhesion. A new STM effort addressing ceramic-metal bond integrity is ongoing with Arizona State (Ig Tsong). At Cornell, Ed Kramer is applying fracture mechanics and neutron reflectivity measurements to understand polymer/glass interface/interphase chemistry and improve bonding strengths in composites and other systems. Problems relating to effects of adhesive tackifiers are being addressed at the University of Akron and imaging of adhesive bonds is being attempted with electron holographic techniques at Stevens Institute of Technology.

D. Non-destructive Evaluation:

The strong subfield emphasis on materials characterization as reviewed above (hydrogen analysis, STM, laser diagnostics etc.) is included in the non-destructive characterization area. An ongoing program in the area is being carried out at the University of Houston (Salama) with the cooperation of the German Frauenhofer Institute for Non-Destructive Analysis in Saarbrucken. Here metal matrix composite third order elastic constants are being measured as a function of temperature. The results are useful in formulating mechanical equations of state for these materials. Additionally, several new small business programs have

been initiated addressing NDE needs in chemical biological materials.

I. New Needs and Directions:

The Army of the next century will require greater mobility, less reliance on logistics, and the ability to project a strong force quickly into a potential troublespot. Such requirements can be translated into lighter weight systems and increased reliability. Higher temperature/pressure operations lead to increased efficiency but also increased stresses on equipment and munitions. New materials including lighter weight ceramic engines, a range of composite materials, graded coatings, and new polymers/elastomers will be required. Novel hard materials such as CVD diamond and cubic boron nitride are already being considered for unusual thermal and wear resistant applications. Smart coatings that provide stealth effects (neural control of color and emissivity), decontamination capabilities, self repair etc. are within the realm of possibility. New non-destructive techniques are required both to assess remaining system life and to provide in-situ monitoring of quality manufacturing. Additional research will be required to improve tribological properties of ceramics. Coatings and camouflage for polymers and polymer composites will have increasing importance. All new materials and systems processing will have to respond to increasing requirements for environmentally benign processing and recyclability. Since systems performance can often be significantly accelerated by technical breakthroughs, it is difficult to say what else to expect. Our ability to construct and characterize materials at the nanolevel will certainly reap future basic research dividends, many of which are now unforeseen.
